

### ? Why

- ✔ If is one of the most used functions in any programming language and PowerApps is not the exception.
- ✔ Test for a specific condition. You can use the If function to execute a single condition.
- ✔ Common examples include:
  - To test if an argument is TRUE or FALSE
  - To output a NUMBER
  - To output some TEXT
  - To output some CALCULATION

### 📖 Overview

- 1 The If function tests if the first condition is met and returns the result. You can define an optional value when all conditions are false.
- 2 So an IF statement can have two results. The first result is if your comparison is True, the second if your comparison is False.
- 3 Nested If - It's called **nested** because you're basically putting an **If** Statement inside another IF Statement and possibly repeating that process multiple times.

The Traffic Light: An Everyday IF Statement

- IF light is **red**, THEN stop!
- IF light is **yellow**, THEN what???
- IF light is **green**, THEN go!

## PowerApps If Function Syntax

### If( logical\_test, value\_if\_true, [value\_if\_false] )

There are 3 parts (arguments) to the If function:

- **logical\_test** something, such as the value in a label or field.
- Specify what should happen if the test result is **true**.
- Specify what should happen if the test result is **false**.

### Logical\_test

**Required.** The value that you want to test. Formula(s) to test for true. Such formulas commonly contain comparison operators (such as <, >, and =) and test functions such as IsBlank and IsEmpty.

When using the IF function to construct a test, we can use the following logical operators:

Operator	Description
=	Equal To
<>	Not Equal To
>	Greater Than
<	Less Than
>=	Greater Than or Equal To
<=	Less Than or Equal To

### value\_if\_true

**Required.** It is the value that is returned if *condition* evaluates to TRUE. The corresponding value to return for a condition that evaluates to true.

The **Value If True** argument can contain just about anything:

- A number

## If function

- Text wrapped in double quotes – “hello”
- A reference to another label or field – Label# or DataCardValue#
- A formula with another IF function.
- A formula with any other combination of functions.

## value\_if\_false

**Optional.** It is the value that is returned if *condition* evaluates to FALSE. The value to return if no condition evaluates to true. If you don't specify this argument, a blank is returned.

### Scenario

1

You have a process where greater than or equal to 50 is a Pass and less than 50 is a fail.

2

You wish to create an automation to return Pass or Fail, depending on the number you input.

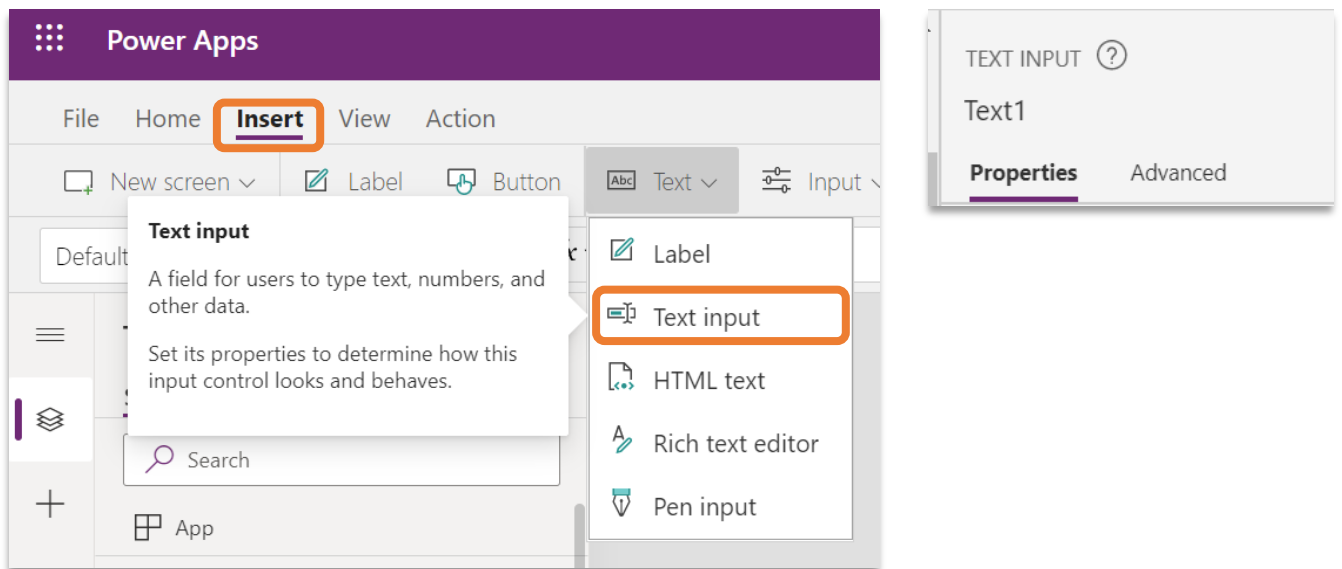

3

You are using PowerApps and navigate to a screen for editing records.

## How?

1. Add a **Text input control**, and name it **Text1** if it doesn't have that name by default. Click **Insert**, Select **Text** and Choose **Text input**.

2. Add a **Label control**, Click **Insert**, Select **Text** and Choose **Text input**.

## If function

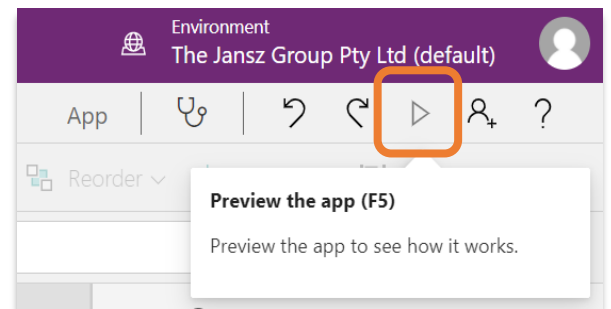

3. Set its **Text** property to this formula:

4. **If( Value(Text1.Text) >=50, "Pass", "Fail")**

Text =  $fx$  If( Value(Text1.Text) >=50, "Pass", "Fail")

5. Click **Preview the App** or press **F5** on keyboard

6. In Text1, type 60.

7. The Label control shows **Pass**, because the value of Text1 is more than 50.

8. In Text1, type 15.

9. The Label control shows **Fail**, because the value of Text1 is less than 50.

## Nested If

The IF function in Excel can be nested, when you have multiple conditions to meet. The FALSE value is being replaced by another IF function to make a further test.

You can only nest 50 If statements. Once you reach this limit, think if you're overcomplicating the overall formula. Re-evaluate the conditions and combine validations into smaller chunks.

The first common use case scenario is to determine where an input value sits within a set of ranges, or bandings. When nesting IF functions, be sure to put the maximum tests first, or the results could be incorrect.

## Scenario

1

You have a range of results from a test.

2

You wish to automatically assign grades based on a set method

3

You want to enter a numerical score to produce the grade.

Grades are assigned as follows:

- **A** - Score greater than 85
- **B** - Score between 84 and 75
- **C** - Score between 74 and 65
- **D** - Score between 64 and 50
- **F** - Score < 50

The English language version of your code reads something like this:

1. If the score is greater than 85 award an A,
2. If not: If the score is [not greater than 85 and ] more than 75 award a B
3. If not: If the score is [not greater than 75 and ] more than 65 award a C
4. If not: If the score is [not greater than 65 and ] more than 50 award a D
5. Otherwise: award an F [ Only scores less than 50 should be left ]

## How?

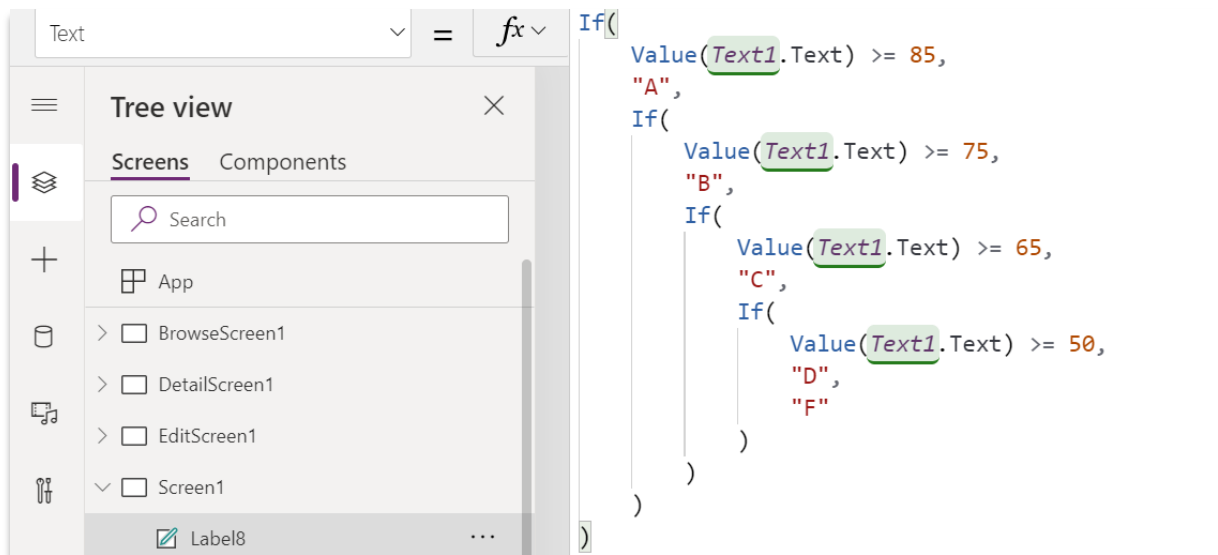

10. From Previous Exercise you have added a **Text input control**, and name it **Text1**.

11. Add a **Label** control, Click **Insert**, Select **Text** and Choose **Text input**.

## If function

12. Set its **Text** property to this formula:

13. **If( Value(Text1.Text) >=85, "A", If( Value(Text1.Text) >=75,"B", If( Value(Text1.Text) >=65,"C", If( Value(Text1.Text) >=50,"D", "F"))))**

14. Click **Preview the App** or press **F5** on keyboard and test out values
